Converting Business Problems into Analytics Solutions

- Converting a business problem into an analytics solution involves answering the following key questions:
 - ① What is the business problem?
 - ② What are the goals that the business wants to achieve?
 - ③ How does the business currently work?
 - ④ In what ways could a predictive analytics model help to address the business problem?

Case Study: Motor Insurance Fraud

In spite of having a fraud investigation team that investigates up to 30% of all claims made, a motor insurance company is still losing too much money due to fraudulent claims.

- What predictive analytics solutions could be proposed to help address this business problem?

- Potential analytics solutions include:
 - Claim prediction
 - Member prediction
 - Application prediction
 - Payment prediction

Assessing Feasibility

- Evaluating the feasibility of a proposed analytics solution involves considering the following questions:
 - 1 Is the data required by the solution available, or could it be made available?
 - 2 What is the capacity of the business to utilize the insights that the analytics solution will provide?

- What are the data and capacity requirements for the proposed Claim Prediction analytics solution for the motor insurance fraud scenario?

- What are the data and capacity requirements for the proposed Claim Prediction analytics solution for the motor insurance fraud scenario?

Case Study: Motor Insurance Fraud

[Claim prediction]

Data Requirements: A large collection of historical claims marked as 'fraudulent' and 'non-fraudulent'. Also, the details of each claim, the related policy, and the related claimant would need to be available.

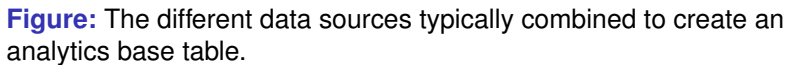

Capacity Requirements: The main requirement is that a mechanism could be put in place to inform claims investigators that some claims were prioritized above others. This would also require that information about claims become available in a suitably timely manner so that the claims investigation process would not be delayed by the model.

Designing the Analytics Base Table

- The basic structure in which we capture historical datasets is the **analytics base table (ABT)**

Descriptive Features						Target Feature
----	----	----	----	----	----	----
----	----	----	----	----	----	----
----	----	----	----	----	----	----
----	----	----	----	----	----	----
----	----	----	----	----	----	----

Figure: The general structure of an **analytics base table**—descriptive features and a target feature.

- The **prediction subject** defines the basic level at which predictions are made, and each row in the ABT will represent one instance of the prediction subject—the phrase **one-row-per-subject** is often used to describe this structure.
- Each row in an ABT is composed of a set of descriptive features and a target feature.
- Defining features can be difficult!

- A good way to define features is to identify the key **domain concepts** and then to base the features on these concepts.

Figure: The hierarchical relationship between an analytics solution, domain concepts, and descriptive features.

- There are a number of general domain concepts that are often useful:
 - Prediction Subject Details
 - Demographics
 - Usage
 - Changes in Usage
 - Special Usage
 - Lifecycle Phase
 - Network Links

Case Study: Motor Insurance Fraud

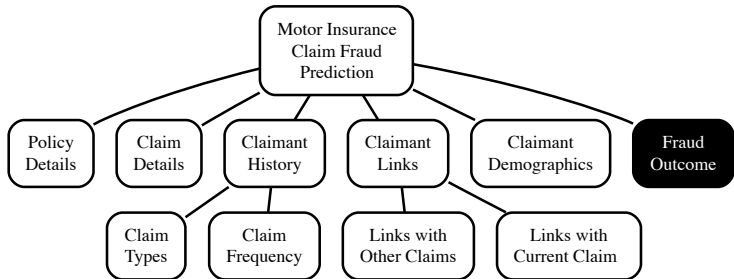

Figure: Example domain concepts for a motor insurance fraud claim prediction analytics solution.

Designing & Implementing Features

- Three key data considerations are particularly important when we are designing features.
 - **Data availability**
 - **Timing**
 - **Longevity**

Different Types of Data

Ordinal						
Ordinal			Categorical			
ID	NAME	DATE OF BIRTH	GENDER	CREDIT RATING	COUNTRY	SALARY
0034	Brian	22/05/78	male	aa	ireland	67,000
0175	Mary	04/06/45	female	c	france	65,000
0456	Sinead	29/02/82	female	b	ireland	112,000
0687	Paul	11/11/67	male	a	usa	34,000
0982	Donald	01/12/75	male	b	australia	88,000
1103	Agnes	17/09/76	female	aa	sweden	154,000

Textual

Interval

Binary

Numeric

Figure: Sample descriptive feature data illustrating numeric, binary, ordinal, interval, categorical, and textual types.

- The features in an ABT can be of two types:
 - **raw features**
 - **derived features**
- There are a number of common derived feature types:
 - **Aggregates**
 - **Flags**
 - **Ratios**
 - **Mappings**

- Many of the predictive models that we build are **propensity models**, which inherently have a temporal element
- For **propensity modeling**, there are two key periods:
 - the **observation period**
 - the **outcome period**

- In some cases the observation and outcome period are measured over the same time for all predictive subjects.

- Often the observation period and outcome period will be measured over different dates for each prediction subject.

(a) Actual

(b) Aligned

Figure: Observation and outcome periods defined by an event rather than by a fixed point in time (each line represents a prediction subject and stars signify events).

- In some cases only the descriptive features have a time component to them, and the target feature is time independent.

(a) Actual

(b) Aligned

Figure: Modeling points in time for a scenario with no real outcome period (each line represents a customer, and stars signify events).

- Conversely, the target feature may have a time component and the descriptive features may not.

Figure: Modeling points in time for a scenario with no real observation period (each line represents a customer, and stars signify events).

- Data analytics practitioners can often be frustrated by legislation that stops them from including features that appear to be particularly well suited to an analytics solution in an ABT.
- There are significant differences in legislation in different jurisdictions, but a couple of key relevant principles almost always apply.
 - 1 **Anti-discrimination legislation**
 - 2 **Data protection legislation**

- Although, data protection legislation changes significantly across different jurisdictions, there are some common tenets on which there is broad agreement which affect the design of ABTs
 - The **collection limitation principle**
 - The **purpose specification principle**
 - The **use limitation principle**

- Implementing a **derived feature**, however, requires data from multiple sources to be combined into a set of single feature values.
- A few key **data manipulation** operations are frequently used to calculate derived feature values:
 - joining data sources
 - filtering rows in a data source
 - filtering fields in a data source
 - deriving new features by combining or transforming existing features
 - aggregating data sources

Case Study: Motor Insurance Fraud

- What are the observation period and outcome period for the motor insurance claim prediction scenario?

Case Study: Motor Insurance Fraud

- What are the observation period and outcome period for the motor insurance claim prediction scenario?
- The observation period and outcome period are measured over different dates for each insurance claim, defined relative to the specific date of that claim.

Case Study: Motor Insurance Fraud

- What are the observation period and outcome period for the motor insurance claim prediction scenario?
- The observation period and outcome period are measured over different dates for each insurance claim, defined relative to the specific date of that claim.
- The observation period is the time prior to the claim event, over which the descriptive features capturing the claimant's behavior are calculated

Case Study: Motor Insurance Fraud

- What are the observation period and outcome period for the motor insurance claim prediction scenario?
- The observation period and outcome period are measured over different dates for each insurance claim, defined relative to the specific date of that claim.
- The observation period is the time prior to the claim event, over which the descriptive features capturing the claimant's behavior are calculated
- The outcome period is the time immediately after the claim event, during which it will emerge whether the claim is fraudulent or genuine.

Case Study: Motor Insurance Fraud

What features could you use to capture the Claim Frequency domain concept?

Figure: Example domain concepts for a motor insurance fraud prediction analytics solution.

Case Study: Motor Insurance Fraud

What features could you use to capture the Claim Details domain concept?

Figure: A subset of the domain concepts and related features for a motor insurance fraud prediction analytics solution.

Case Study: Motor Insurance Fraud

- The following table illustrates the structure of the final ABT that was designed for the motor insurance claims fraud detection solution.
- The table contains more descriptive features than the ones we have discussed
- The table also shows the first four instances.
- If we examine the table closely, we see a number of strange values (for example, -9 999) and a number of missing values—we will return to these in Chapter 3.

Table: The ABT for the motor insurance claims fraud detection solution.

ID	TYPE	INC.	MARITAL STATUS	NUM. CLMNTS.	INJURY TYPE	HOSPITAL STAY	CLAIM AMT.
1	CI	0	Married	2	Soft Tissue	No	1 625
2	CI	0		2	Back	Yes	15 028
3	CI	54 613		1	Broken Limb	No	-9 999
4	CI	0		3	Serious	Yes	270 200
			⋮			⋮	

ID	TOTAL CLAIMED	NUM. CLAIMS	NUM. CLAIMS 3 MONTHS	AVG. CLAIMS PER YEAR	AVG. CLAIMS RATIO	NUM. SOFT TISSUE	% SOFT TISSUE
1	3 250	2	0	1	1	2	1
2	60 112	1	0	1	1	0	0
3	0	0	0	0	0	0	0
4	0	0	0	0	0	0	0
			⋮			⋮	

ID	UNSUCC. CLAIMS	CLAIM AMT. REC.	CLAIM DIV.	CLAIM TO PREM.	REGION	FRAUD FLAG
1	2	0	0	32.5	MN	1
2	0	15 028	0	57.14	DL	0
3	0	572	0	-89.27	WAT	0
4	0	270 200	0	30.186	DL	0
		⋮			⋮	

Summary

- Predictive data analytics models built using machine learning techniques are tools that we can use to help make better decisions within an organization, not an end in themselves.
- It is important to fully understand the business problem that a model is being constructed to address—this is the goal behind *converting business problems into analytics solutions*

- Predictive data analytics models are reliant on the data that is used to build them—the **analytics base table (ABT)**.
- The first step in designing an ABT is to decide on the **prediction subject**.
- An effective way in which to design ABTs is to start by defining a set of **domain concepts** in collaboration with the business, and then designing **features** that express these concepts in order to form the actual ABT.

- Features (both descriptive and target) are concrete numeric or symbolic representations of domain concepts.
- It is useful to distinguish between **raw features** that come directly from existing data sources and **derived features** that are constructed by manipulating values from existing data sources.
- Common manipulations used in this process include aggregates, flags, ratios, and mappings, although any manipulation is valid.

- The techniques described here cover the **Business Understanding**, **Data Understanding**, and (partially) **Data Preparation** phases of the **CRISP-DM** process.

Figure: A diagram of the CRISP-DM process.

Figure: A summary of the tasks in the Business Understanding, Data Understanding, and Data Preparation phases of the **CRISP-DM** process.
